## **Abstract**

In this paper we set out to examine the sandwich views of students and teachers at William Lyon Mackenzie C.I.

Our study consisted of a survey conducted both in person and online with 140 participants. We asked participants basic demographic information about where they fit into the William Lyon Mackenzie Collegiate Institute community, and examined correlations between sandwich views and demographics.

We propose the creation of a two-dimensional sandwich alignment chart, inspired by two-dimensional political axes. The sandwich alignment chart has a dimension for “sandwich purity”, and “sandwich orthodoxy”.

We hypothesize that:

1. Sandwich purity and sandwich orthodoxy will be positively correlated.
2. Students in the MaCS or Gifted program are more likely to have a low orthodoxy score.

We believe the first hypothesis to be true because we believe those with a pure definition of a sandwich will also have an orthodox definition. We believe the second hypothesis to be true because we believe that students in those programs tend to challenge societal norms more so than most.

# Part I

## Introduction

# Chapter 1

## Purpose

### 1.1 The failure of the dictionary

We find dictionary definitions to be insufficient, as they are either too restrictive, or too vague.

The Oxford English Dictionary [10] restrictively defines a sandwich as:

An item of food consisting of two pieces of bread with a filling between them, eaten as a light meal.

Whereas The Free Dictionary [35] more broadly defines a sandwich as:

- a. Two or more slices of bread with a filling such as meat or cheese placed between them.
- b. A partly split long or round roll containing a filling.
- c. One slice of bread covered with a filling.

Since the Oxford English Dictionary definition requires two pieces of bread, this excludes sub sandwiches, which most would consider a sandwich. This makes the Oxford definition too restrictive.

Also, both definitions fail to adequately define “filling”. The Free Dictionary gives meat and cheese as examples, but many people put lettuce and tomato in their sandwiches, neither of which are meat or cheese.

So, dictionary definitions of “sandwich” are insufficient to determine what a sandwich is.

## 1.2 Legal background

The question of what is a sandwich has been the centre of several legal publications. We believe that these publications have failed to provide a strong definition of what a sandwich is, and they contradict each other.

For tax purposes, the New York State Department of Taxation and Finance [31] says:

*Sandwiches* include cold and hot sandwiches of every kind that are prepared and ready to be eaten, whether made on bread, on bagels, on rolls, in pitas, in wraps, or otherwise, and regardless of the filling or number of layers. A sandwich can be as simple as a buttered bagel or roll, or as elaborate as a six-foot, toasted submarine sandwich.

Some examples of taxable sandwiches include:

- common sandwiches, such as:
  - BLTs (bacon, lettuce, and tomato sandwiches);
  - club sandwiches;
  - cold cut sandwiches;
  - grilled cheese sandwiches;
  - peanut butter and jelly sandwiches
  - salad-type sandwiches (e.g., chicken, egg, ham, and tuna);
- bagel sandwiches (served buttered or with spreads, or otherwise as a sandwich);
- burritos
- cheese-steak sandwiches;
- croissant sandwiches;
- fish fry sandwiches;
- flatbread sandwiches;

- breakfast sandwiches;
- gyros;
- hamburgers on buns, rolls, etc.;
- heroes, hoagies, torpedoes, grinders, submarines, and other such sandwiches;
- hot dogs and sausages on buns, rolls, etc.;
- melt sandwiches;
- open-faced sandwiches;
- panini sandwiches;
- Reuben sandwiches; and
- wraps and pita sandwiches.

This is a very broad definition, but it is also quite comprehensive and informative. It is important to note that [31] defines burritos as sandwiches. However, other legal cases contradict this definition.

A case in the Commonwealth of Massachusetts Superior Court entitled *White City Shopping Center, LP v. PR Restaurants, LLC dba Bread Panera* [49] involved two companies in a dispute over whether or not burritos are sandwiches. In this case, the court ruled that burritos are not sandwiches. This contradicts the definition in New York State tax law. So, we can clearly see that there is no legal consensus on this matter.

Furthermore, the legal scholar Marjorie Florestal argues that the decision of the *White City* case is rooted in classist and racial views of sandwich cuisine [16]:

The burrito meets resistance not just because of its class but also because of its race—and the way the two play off each other.

So, we have established that the definition of a sandwich is inconclusive among both the linguist and legal communities [10, 35, 31, 49]. The question is also of importance for better understanding class systems and race in our society [16].

# Chapter 2

## Terminology and definitions

This chapter will explain any terminology and definitions we use throughout this paper.

### 2.1 Question types

**Demographic question** A demographic question is any of the non-food questions asked in our survey. These questions asked about participants demographics, in order to examine any correlations between demographics and sandwich views.

**Food question** A food question is any question asked about sandwiches or their ingredients. We asked 43 food questions as a part of this study. Participants answered each question on a 0 to 10 scale. We purposely started the scale at 0 so as to make 5 exactly in the middle of the range of possible responses.

### 2.2 Variables

The demographic questions are our independent variables. We mainly look at academic stream, grade, and race as our independent variables.

The food questions are used to calculate orthodoxy and purity, which are our dependent variables.

We also consider the correlation between our two dependent variables to gain a deeper understanding of how they relate.

## **2.3 Population of interest**

Our population of interest is both students and teachers at William Lyon Mackenzie C.I.

# Chapter 3

## Methodology

### 3.1 Survey type

We conducted our survey as mix of a stratified, voluntary, and random sample. We surveyed roughly 10% of the William Lyon Mackenzie population. With a sample size this large, most bias should be eliminated.

We aimed for a stratified sample of academic streams. Unfortunately, we failed to collect a perfectly stratified sample of streams. However, we did perform an analysis of the data and found that to be inconsequential.

According to the William Lyon Mackenzie student services department, roughly 26.67% of the students at the school are in the MaCS program. 10.37% are in the Gifted program. 62.96% are in some other program. There are roughly 1350 students at the school. We could not find information on the number of teachers, but we estimate it to be between 60 and 70.

We made manual changes to categorical data to correct for similar, blank, and inappropriate responses. As part of this, we grouped ethnicity into the following 11 categories: Caucasian, Chinese, East Asian, Filipino, Jewish, Korean, Middle Eastern, Mixed, Other, South Asian, and Vietnamese.

### Demographic questions

For demographic information, we asked participants for their grade (with teacher as an option), favourite subjects, and ethnic background. We asked students for their academic stream, and teachers for their department.

Since the number of teachers surveyed was small, we do not do any analysis on teachers departments, and instead treat them as a separate grade and academic stream. We also do not analyze the data on favourite subjects since it is very noisy (see figure 3.1 on the following page).

Figure 3.1: A bar plot of subjects, showing the noisiness and uselessness of the subject data.

## Food questions

We asked respondents 43 questions related to sandwiches and their ingredients. We use all of this data.

# Chapter 4

## Metrics

### 4.1 Axes metrics

We have two metrics used in our calculations: purity and orthodoxy.

Purity is how pure a respondent's definition of a sandwich is. The less things a respondent considers a sandwich, the greater their purity score will be. Similarly, the more things a respondent considers a sandwich, the lower their purity score will be.

Orthodoxy is a measure of how much a respondent differs from the mean set of responses. The less a respondent's answers differ from the mean set of answers, the greater their orthodoxy score will be. Similarly, the more a respondent's answers differ from the mean set of answers, the lower their orthodoxy score will be.

Both purity and orthodoxy are bound in the range  $[-1, 1]$ .

We describe the general scoring system in subsection 4.1.1. This scoring system is used to calculate the purity metric described in subsection 4.1.2 on the following page and the orthodoxy metric described in subsection 4.1.3 on page 11.

#### 4.1.1 Scoring

While participants answered each food question on a 0 to 10 scale, it is more convenient to perform calculations using a  $-5$  to  $5$  scale. We converted responses from the 0 to 10 scale to the  $-5$  to  $5$  scale by subtracting each response from 5.

Formally, for each response to a food question, we calculate the score for the response by the passing the response through the sandwich spectrum function, defined in definition 1 on the following page.

**Definition 1** (Sandwich spectrum function). The sandwich spectrum function is defined as:

$$s : \{x \in \mathbb{R} \mid 0 \leq x \leq 10\} \rightarrow \{x \in \mathbb{R} \mid -5 \leq x \leq 5\} \text{ by } s(x) = 5 - x \quad (4.1)$$

Due to the format of our survey, all responses are integers, and are mapped to another integer by the sandwich spectrum function. Although, in principle, the sandwich spectrum function works for real numbers as well.

We can create a table for  $s$ :

$x$	0	1	2	3	4	5	6	7	8	9	10
$s(x)$	5	4	3	2	1	0	-1	-2	-3	-4	-5

One will note that this gives responses that were originally high a lower score. This is intentional. Subsection 4.1.2 will show it to be useful for calculating the purity metric, and subsection 4.1.3 on the following page will show it to be irrelevant for calculating the orthodoxy metric.

## 4.1.2 Purity

The purity score for a respondent is defined as the sum of a respondent's scores divided by the maximum possible score.

The maximum score for a question is 5, and there are 43 food questions. This means that the maximum possible score is  $43 \times 5 = 215$ .

**Definition 2** (Sadwich purity function). Let  $A$  be the set of 43 food answers, each of which is a vector in  $\mathbb{R}^{43}$ .

Then, we define the sandwich purity function as:

$$p : \mathbb{R}^{43} \rightarrow \mathbb{R} \text{ by } p(A) = \frac{\sum_{i=1}^{43} A_i}{215} \quad (4.2)$$

This definition illustrates why we subtract each response from 5 to get the score. The sandwich spectrum function will assign higher scores for lower responses. The purity function assigns greater purity values for higher scores. Since a lower response to a question implies a more pure definition of a sandwich, definition 1 is a valid metric for scoring.

### 4.1.3 Orthodoxy

To calculate orthodoxy for each respondent, we take the score for each question as a dimension of a vector, which creates a vector in 43-dimensional Euclidean space.

We also calculate the mean response for each question, and create an additional  $\mathbb{R}^{43}$  vector from that. This vector is referred to as the mean vector, and denoted as  $\vec{m}$ .

The orthodoxy score for a respondent is defined as the cosine similarity between the respondent's  $\mathbb{R}^{43}$  vector and  $\vec{m}$ .

**Definition 3** (Mean vector). To calculate the value of the mean vector,  $\vec{m}$ :

Let  $A \in \mathbb{R}^{43}$  be the set of response vectors. Then,  $n(A)$  is the cardinality of the set  $A$ .

Then:

$$\vec{m} = \frac{\sum_{i=1}^{n(A)} A_i}{n(A)} \quad (4.3)$$

**Definition 4** (Sandwich orthodoxy function). To calculate the orthodoxy score for a respondent:

Let  $\vec{r}$  be a vector in  $\mathbb{R}^{43}$  defined as having each of its components equal to the score for each food question.

$$o : \mathbb{R}^{43} \rightarrow \mathbb{R} \text{ by } o(\vec{r}) = \frac{\vec{r} \cdot \vec{m}}{\|\vec{r}\| \|\vec{m}\|} \quad (4.4)$$

Since we are calculating orthodoxy as the cosine of the angle between two vectors, it is useful to have some vector components be negative, as that allows respondents to have a negative orthodoxy score if they answer opposite to the mean response. It does not matter what direction the vectors are in, as we are only looking at the angle between them. This means that the sandwich spectrum function could have been defined as subtracting 5 instead of subtracting from 5 for the purposes of the orthodoxy function. Since both definitions would have worked for orthodoxy, we stick with definition 1 on the preceding page for the sake of consistency with the purity metric.

## Part II

### Results Summary

# Chapter 5

## Results summary

All numbers in this chapter have been rounded to 5 digits after the decimal point.

### 5.1 Summary with outliers

Table 5.1: A summary of all respondents with outliers included.

# Chapter 6

## Demographic breakdowns

The demographic breakdowns presented in this chapter are with outliers removed.

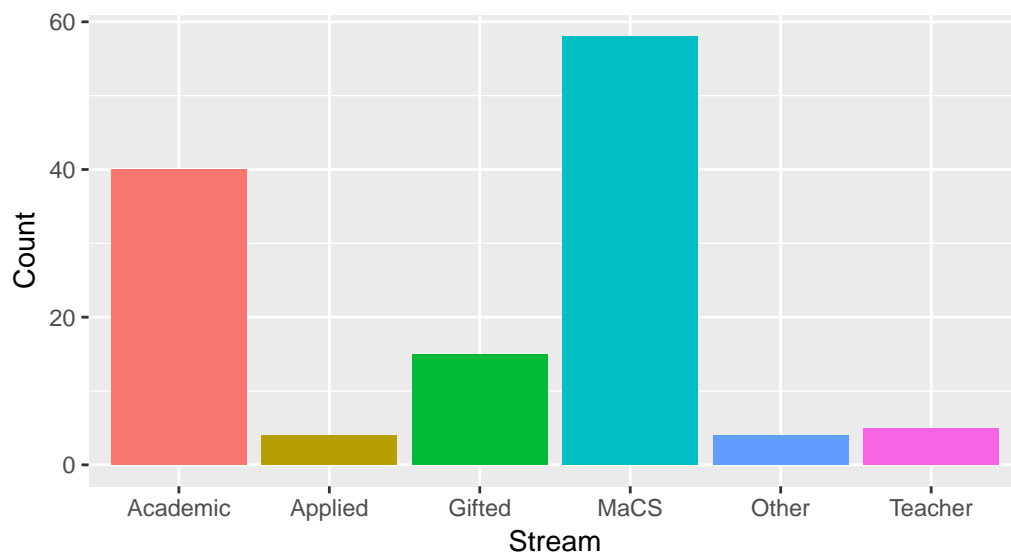

Figure 6.1: A bar chart of academic streams.

Figure 6.2: A bar chart of grades.

Figure 6.3: A bar chart of ethnic backgrounds.

## Part III

### Hypothesis 1

# Chapter 7

## Models

We will use two models to analyze the relationship between purity and orthodoxy.

The first model we will use is a linear model. This allows us to see the general trend of the correlation.

The second model we will use is a quadratic model. This allows us to see more detailed results of how sandwich purity and sandwich orthodoxy are intertwined.

As we will see when we begin applying these two models in chapter 8 on the next page, the quadratic model is significantly more accurate overall. However, the linear model is useful for analyzing responses that do not significantly differ from the norm. The linear model also shows whether the correlation between purity and orthodoxy is positive or negative.

# Chapter 8

## Outliers

We begin our analysis by plotting the purity vs orthodoxy and performing a linear, quadratic, and locally weighted analysis in figure 8.1.

The solid red curve is the result of the locally weighted analysis, and the shaded area is the 99% confidence interval for that analysis. The dashed black line is the result of the linear line of best fit. The dotted blue line is the result of the quadratic curve of best fit.

### 8.1 With outliers

Figure 8.1: A plot of purity vs orthodoxy with data points coloured based on stream.

The linear regression has a positive slope, which proves the first hypothesis that purity and orthodoxy are positively correlated. We will investigate the significance of the correlation in chapter 9 on page 23.

## **8.1.1 Correlation calculations including outliers**

We use the program in section C.9 on page 60 to calculate the numbers in this subsection.

### **8.1.1.1 Linear model**

#### **8.1.1.1.1 Equation of the linear model**

$$y \approx 0.100\,952\,8x + 0.680\,094\,7$$

#### **8.1.1.1.2 $r$ values of the linear model**

$$r \approx 0.125\,253\,454\,074\,209$$

$$r^2 \approx 0.015\,688\,427\,757\,52$$

### **8.1.1.2 Quadratic model**

#### **8.1.1.2.1 Equation of the quadratic model**

$$y \approx -1.302\,536\,6x^2 + 0.336\,354\,4x + 0.675\,795\,0$$

#### **8.1.1.2.2 $r^2$ value of the quadratic model**

$$r^2 \approx 0.250\,957\,589\,793\,36$$

## 8.2 Identifying outliers

From this analysis, it is clear that some respondents are highly deviant. We next use the quadratic mode to create a residual plot in figure 8.2.

Figure 8.2: A residual plot using the quadratic regression analysis method.

We calculate the interquartile range of the residuals and remove any data that are 1.5 times the ICQ above the third quartile or 1.5 times the ICQ below the first quartile. This is done using the program in section C.8 on page 59. This program then creates a new file for analyzing with the following respondents removed: 7, 51, 59, 62, 64, 69, 81, 82, 83, 103, 113, 120, 125, and 130.

## 8.3 Outliers removed

We once again plot orthodoxy vs purity by stream in figure 8.3 on the next page, this time with the outliers removed.

Figure 8.3: A plot of purity vs orthodoxy with data points coloured based on stream. Outliers have been removed.

The solid red curve is the result of the locally weighted analysis, and the shaded area is the 99% confidence interval for that analysis. The dashed black line is the result of the linear line of best fit. The dotted blue line is the result of the quadratic curve of best fit.

### 8.3.1 Correlation calculations with outliers removed

We use the program in section C.9 on page 60 to calculate the numbers in this subsection.

#### 8.3.1.1 Linear model

##### 8.3.1.1.1 Equation of the linear model

$$y \approx 0.113\,899\,9x + 0.736\,064\,0$$

#### 8.3.1.1.2 $r$ values of the linear model

$$r \approx 0.209\,580\,523\,324\,373$$

$$r^2 \approx 0.043\,923\,995\,756\,918$$

Despite the low  $r$  value for the linear model, chapter 9 on the next page shows that this result is not an accident, and our result is significant enough to draw conclusions from.

#### 8.3.1.2 Quadratic model

##### 8.3.1.2.1 Equation of the quadratic model

$$y \approx -1.351\,228\,9x^2 + 0.363\,313\,5x + 0.730\,316\,5$$

##### 8.3.1.2.2 $r^2$ value of the quadratic model

$$r^2 \approx 0.651\,494\,497\,892\,727$$

### 8.4 Effect of outliers on the data

Removing the outliers does not significantly effect the curves due to the high sample size. However, it does greatly increase the accuracy of the model and only a handful of points were removed. This is especially notable in the  $r^2$  value for the quadratic model, which more than doubles.

Unless otherwise specified, the rest of this paper will be excluding outliers from calculations.

# Chapter 9

## Significance

From the somewhat low magnitude of the  $r$  and  $r^2$  values, the results in chapter 8 on page 18 may not seem significant at first.

However,  $r$  and  $r^2$  only show the strength of the correlation, not the significance.

To calculate the significance of our results, we must calculate the  $p$ -value for both our linear and quadratic models.[34]

If the  $p$ -value of a correlation is less than 0.05, then it is considered to be significant, and not accidental. A  $p$ -value less than 0.05 is strong evidence against the null hypothesis.[34]

We can use the program from section C.9 on page 60 to calculate the  $p$ -values.

### 9.1 Linear model

The  $p$ -value for the linear model as reported by the R code in section C.9 on page 60 is:

$$p \approx 0.018\,507\,249\,670\,159\,3$$

This is less than 0.05, which means that this result is significant. This proves that our first hypothesis is correct. While the correlation is not incredibly strong, the low  $p$ -value proves it to be non-accidental.

Sandwich purity and sandwich orthodoxy have a significant weak positive correlation.

## 9.2 Quadratic model

The  $p$ -value from the quadratic model as reported by the R code in section C.9 on page 60 is:

$$p < 2.2 \times 10^{-16}$$

R fails to calculate the exact  $p$ -value because it is so small that computers are incapable of accurately calculating it.

This  $p$ -value is much less than 0.05, which demonstrates that our quadratic model is incredibly accurate. This tells us that it was a good choice to use a quadratic model for the residual analysis in section 8.2 on page 20.

# Part IV

## Hypothesis 2

# Chapter 10

## Orthodoxy and academic stream

### 10.1 Ranges

Figure 10.1: A box and whiskers plot of orthodoxy broken down by academic stream.

Figure 10.1 is inconclusive towards concluding if our second hypothesis is true or false. MaCS students have a slightly higher orthodoxy than most other groups, and gifted students have a lower orthodoxy. However, the difference is very small. Next we will look at the mean responses to try to reach a stronger result.

## 10.2 Means

Figure 10.2: A plot of mean orthodoxy broken down by academic stream.

Figure 10.2 is also inconclusive towards concluding if our second hypothesis is true or false. The difference between groups is too small to call significant. So, we do either do not have sufficient data to say if there is a correlation between academic stream and orthodoxy, or there is no correlation.

Our second hypothesis is inconclusive.

# Part V

## Conclusion

# Chapter 11

## Conclusion

### 11.1 The sandwich topic

While sandwich views may at first seem to be a frivolous topic, it has the unique property of being immensely fascinating. This allowed us to conduct a survey with many questions, obtaining a high quantity of quality numerical data for analysis.

### 11.2 Conclusions of our analysis

We conclude that our first hypothesis is true, and our second is inconclusive.

### 11.3 Further research

Our data set provides the possibility for further research into trends between ethnicity and specific questions. For example, it looks like the relationship between ethnicity and whether or not chicken foot is a sandwich ingredient may have some interesting trends.

### 11.4 Improvements to the study

To improve this study, we would try asking the questions about subjects in a different manner so we could collect more meaningful responses on it.

### 11.4.1 Removing bias

Because our survey was in part a convenience sample and also partially a voluntary sample, we introduced a fair degree of bias into the study. This includes biases such as voluntary response bias and sampling bias. We believe that the large sample size counteracts that to a large enough degree that we are confident in our general results. However, a simple random sample would likely provide more accurate numbers for the exact  $r$  and  $r^2$  values for instance.

# Part VI

## Appendices

# Appendix A

## Questions

### A.1 Sandwich Survey

What defines a sandwich?

### A.2 Demographic Information

We need to study correlations and demographics.

#### A.2.1 What grade are you in?

*Respondents were asked to select only one option.*

- ☐ Grade 9    ☐ Grade 10    ☐ Grade 11    ☐ Grade 12    ☐ Teacher

#### A.2.2 What is/are your favourite subjects?

Answer based on what department teaches the subject at Mackenzie.

*Respondents were asked to check all that apply.*

- |                                                             |                                               |
|-------------------------------------------------------------|-----------------------------------------------|
| <input type="checkbox"/> Arts                               | <input type="checkbox"/> Business             |
| <input type="checkbox"/> Computer Science and<br>Technology | <input type="checkbox"/> Co-op and Leadership |
| <input type="checkbox"/> English                            | <input type="checkbox"/> Languages            |
| <input type="checkbox"/> Library                            | <input type="checkbox"/> Math                 |
| <input type="checkbox"/> Physical Education                 | <input type="checkbox"/> Science              |
| <input type="checkbox"/> Social Sciences                    | <input type="checkbox"/> Special Education    |
| <input type="checkbox"/> Other: _____                       |                                               |

### **A.2.3 What is your ethnic background?**

*Respondents were asked to provide a free response.*

---

## **A.3 Student Questions**

*Questions in this section were asked only of respondents who identified as being in grade 9, 10, 11, or 12. It was not asked of respondents who identified as a teacher.*

### **A.3.1 What is your academic stream?**

Select whatever option you most closely identify with.

*Respondents were asked to select only one option.*

- ☐ Applied
- ☐ Academic
- ☐ MaCS
- ☐ Gifted
- ☐ Other: \_\_\_\_\_

## A.4 Teacher Questions

*Questions in this section were asked only of respondents who identified as being a teacher. It was not asked of respondents who identified as being in grade 9, 10, 11, or 12.*

### A.4.1 What departments do you work in at Mackenzie?

Answer based on what department teaches the subject at Mackenzie.

*Respondents were asked to check all that apply.*

- |                                              |                                          |                                                             |

## B.2 Data without outliers

See chapter 8 on page 18 for an explanation of how we identified and removed outliers.

Table B.2: The results of all respondents with outliers removed. Teachers had their stream set to “Teacher”.

#	Purity	Orthodoxy	Grade	Background	Stream
